Results of multiple biopsy sampling in the characterization of breast lesions. The purpose of this study was to compare the value of multiple biopsy sampling with one core needle biopsy alone in the characterization of breast lesions. Of the 92 patients referred for core needle biopsy of 91 breast lesions, 61 (67%) had multiple biopsies. Lesions were classified as malignant or benign based on the results of the most extensive biopsy. The incidence of malignancy was similar in single (21/61; 34%) and multiple (14/61; 23%) biopsies ( $p = 0.153$ ). However, the cancer detection rate was higher in multiple biopsies in patients with microcalcifications (19 of 25 [76%] vs 10 of 32 [31%];  $p = 0.001$ ), distortions (27 of 30 [90%] vs 15 of 31 [49%];  $p = 0.001$ ), spiculated lesions (30 of 37 [81%] vs 12 of 35 [34%];  $p = 0.0001$ ), asymmetric lesions (14 of 26 [54%] vs 3 of 27 [11%];  $p = 0.0001$ ), and suspicious masses (14 of 22 [64%] vs 4 of 18 [22%];  $p = 0.011$ ). Thus, additional biopsies may be helpful in the evaluation of benign breast lesions with microcalcifications, distortions, spiculated lesions, asymmetric lesions, and suspicious masses.
