Single-ion hydration forces are calculated as water and electrolyte molecules approach and interact with a proton in aqueous solutions, from room temperature to near boiling point. We compare the force with that of the widely used site-site potential that assumes no attractive force beyond the first solvation shell. The behavior of the force is studied as a function of ion radius, temperature, concentration, and salt, and it is found that the force exhibits significant variation due to temperature, ion radius, and concentration. The forces are more attractive when the ion radius is large and the concentration is high, in agreement with experimental observations for high concentration and high temperature. The site-site potential is seen to give a qualitatively good description of the force. In addition, we propose a
